

Description of Bike Count Prediction Data

Bike-sharing systems are a means of renting bicycles where the process of obtaining membership, rental, and bike return is automated via a network of kiosk locations throughout a city. Using these systems, people are able to rent a bike from one location and return it to a different place on an as-needed basis. Currently, there are over 500 bike-sharing programs around the world.

The data generated by these systems make them attractive for researchers because of the duration of travel, departure location, arrival location, and time elapsed is explicitly recorded. Bike-sharing systems therefore function as a sensor network, which can be used for studying mobility in a city.

Problem Statement

In this project, you are asked to combine historical usage patterns with weather data in order to forecast hourly bike rental demand.

Data

You are provided with the following files:

1. train.csv : Use this dataset to train the model. This file contains all the weather-related features as well as the target variable "count". The training dataset is comprised of the first 18 months.
2. test.csv : Use the trained model to predict the count of total rentals for each hour during the next 6 months.

Data Dictionary

Here is the description of all the variables :

Variable	Definition
datetime	hourly date + timestamp
season	Type of season (1 = spring, 2 = summer, 3 = fall, 4 = winter)
holiday	whether the day is considered a holiday
workingday	whether the day is neither a weekend nor holiday
weather	weather
temp	temperature in Celsius
atemp	"feels like" temperature in Celsius
humidity	relative humidity
windspeed	wind speed
casual	number of non-registered user rentals initiated
registered	number of registered user rentals initiated
count	number of total rentals
